Lipshutz et al. Anesthesiology 2009;110:408-21

Précoce

- *Quelques heures après début de la chirurgie*
- *Peropératoire, postopératoire immédiat,…*

Persiste plusieurs jours après chirurgie (2-3 semaines)

Insulino-résistance périphérique
(tissus insulino-dépendants périphériques)
muscle squelettique, tissu adipeux

Facteurs aggravants

- *Obésité (tissu adipeux +++)*
- *Chirurgie invasive (hémorragique, longue durée, hémodynamiquement intense, circulation extra-corporelle, …)*
- *Jeun préopératoire prolongé (en limiter le temps ou apport glucosé…)*
- *Hypothermie*
- *Immobilisation prolongée (réhabilitation précoce)*

Left to right: Grunkemeier, Furnary, Wu, Gao, Zerr (*front ro*

4. *Cardiac-related mortality* referred to all deaths in which arrhythmia or pump failure was identified as the seminal cause of death.

Study Groups

All patients with DM were divided into two sequential groups according to the type of perioperative glycemic control that they received.

Subcutaneous insulin group. Patients operated on between January 1987 and September 1991, the subcutaneous insulin (SQI) group (n = 942), received subcutaneous insulin injections every 4 hours in a directed attempt to maintain blood glucose levels below 200 mg/dL. Sliding scale dosage of insulin was titrated to each patient's glycemic response during the previous 4 hours. These sliding scale SQI injections were continued every 4 hours throughout the patients' hospital course, even after the resumption of their preoperative glucose control regimen.

CII group. All patients with DM undergoing CABG operated on between October 1991 and December 2001, the CII group (n = 2612), received a CII infusion titrated per protocol in the perioperative period (Portland protocol).[16] The current Portland protocol

patient was transferred to the telemetry unit. In January 1996, the protocol was expanded with initiation in the operating room (before sternotomy and after induction of anesthesia, with continuation during cardiopulmonary bypass) and uniform continuation until 7 AM of the third POD, even for patients who had transferred out of the ICU.

set. By means of this nationally recognized risk assessment, all patients were assigned an expected probability of death. Predicted and observed hospital mortalities were then compared, along with the observed/expected risk ratios. The composite STS risk score was calculated as the logit of the probability of death.

Univariate analyses between groups were done with *t* tests and χ^2 analyses. The Bonferroni correction was applied to adjust for multiple comparisons between groups. Stepwise logistic regression was used to produce risk models for hospital death. to measure model discrimination, c-statistics (area under the receiver operating characteristic curve) were used, and the Hosmer-Lemeshow statistic was used to measure calibration.[17] The purpose was to make internal comparisons rather than to produce a prediction equation for use outside of this data set. Thus all patients were used, rather than separating the data into training and testing subsets or applying shrinkage methods to the coefficients. All statistical analyses were performed with SPSS software (version 10.0; SPSS, Inc, Chicago, Ill).

Results

Data Analysis

In-hospital mortality was the primary end point of this study. Patient groups were analyzed on an intent-to-treat basis. According to this method, intraoperative and first POD deaths were included in the end point analysis even though those patients did not complete the 3-day SQI or CII treatment protocols. This was considered to be the most rigorous method to test our hypothesis.

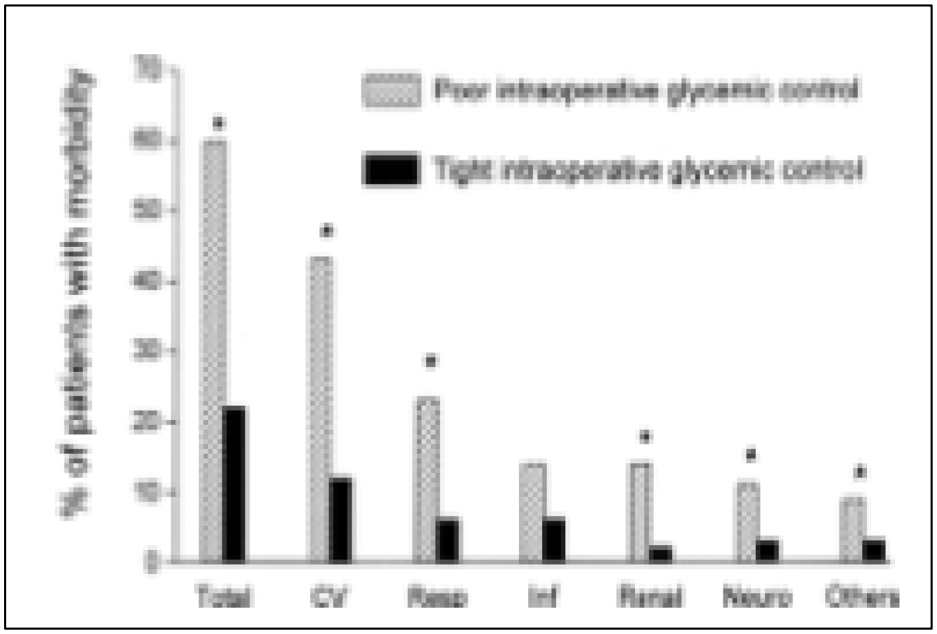
An internal logistic regression model was developed to determine the effect of perioperative hyperglycemic treatment method (SQI vs CII) on operative mortality after adjustment for other known preoperative risk factors. The external risk model was taken from the 1996 STS risk algorithm.[2] The 1996 model was chosen because that year contained the median patient of the study's data

room or within 24 hours of surgery (n = 24) had "operative catastrophes" and did not survive long enough to derive a benefit from initiation of CII therapy. If our analysis were to be evaluated on an actual treatment (as opposed to intent-to-treat) basis, SQI mortality would have been 4.5% (n = 42/934), and CII mortality would have been 1.9% (n = 49/2596, $P < .0001$).

Cause of Death

The seminal causes of death for each of the 115 patients who died were pump failure in 54% (n = 62), arrhythmia in 17% (n = 20), neurologic causes in 19% (n = 22), respiratory failure in 5% (n = 6), renal failure in 3% (n = 3),

Poor Intraoperative Blood Glucose Control Is Associated with a Worsened Hospital Outcome after Cardiac Surgery in Diabetic Patients



Poor intraoperative glucose control was defined by > 200 $mg.dL^{-1}$

Intensive Intraoperative Insulin Therapy versus Conventional Glucose Management during Cardiac Surgery

A Randomized Trial

Ann Intern Med. 2007;146:233-243.

Gunjan Y. Gandhi, MD, MSc; Gregory A. Nuttall, MD; Martin D. Abel, MD; Charles J. Mullany, MD; Hartzell V. Schaff, MD; Peter C. O'Brien, PhD; Matthew G. Johnson, MPH; Arthur R. Williams, PhD; Susanne M. Cutshall, RN; Lisa M. Mundy, RN; Robert A. Rizza, MD; and M. Molly McMahon, MD

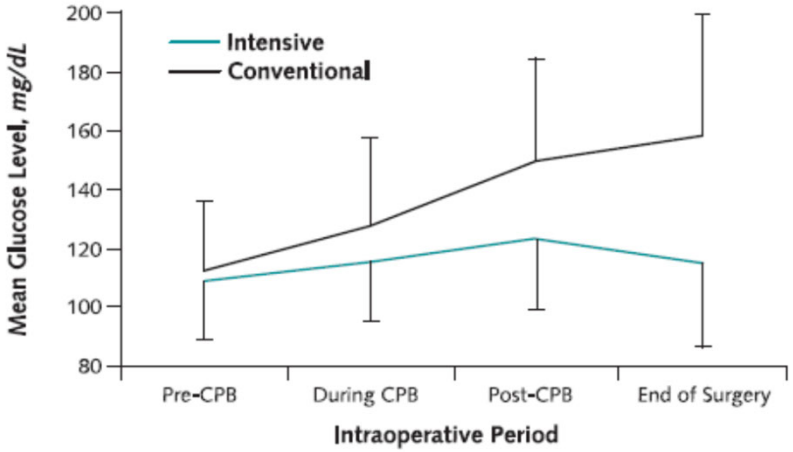
Etude prospective, randomisée, unicentrique (Rochester, MN)

Chirurgie cardiaque avec CEC (n=400)

- Groupe insulinothérapie intensive si BGL>100 mg/dl (80-100 mg/dl)
- Groupe conventionnel insulinothérapie si BGL >200 mg/dl (<150 mg/dl)

Contrôle glycémique strict postopératoire (80-110 mg/dl) pdt 24 heures

Critères de jugement (composite) : morbi-mortalité postopératoire à 30 jours



Hypoglycémie

- perop: n=1 dans chaque groupe

- postop: n=8 (intensive)
  n=14 (conventionnel)

Table 4. **Comparison of Primary and Secondary Outcomes***

Outcome	Intensive Treatment Group (n = 185), n (%)	Conventional Treatment Group (n = 186), n (%)	Relative Risk or Odds Ratio (95% CI)†	P Value‡

Pas de différence significative sur la durée de séjour en réa ou à l' hôpital

Because of cardiopulmonary bypass (CPB)-induced alterations in insulin secretion and resistance, profound hyperglycemia occurs in patients undergoing cardiac surgery (levels may approach 1000 mg/dL). Hyperglycemia has been shown to worsen neurologic injury after focal and global cerebral ischemia, probably because of anaerobic glycolysis-induced conversion of glucose to lactate, which causes intracellular acidosis and impairment of cellular metabolism (1,2). The appropriate

intraoperative management of hyperg
whether it adversely affects neurologic o
tients after cardiac surgery, remains co
7).[1,2,3] Previous investigations have asses
injury as either perioperative gross neurol
perioperative changes in a battery of neu
examinations. However, interpretation ar
nificance of perioperative changes in neu

Attempting intraoperative tight glucose control may be difficult

Intraoperative insulin resistance (hypothermia, stress hormone, CPB…)

Postoperative requirement (insulin ristance) may decrease rapidly

Risk of postoperative hypoglycemia

Protocole d'insulinothérapie IVSE EN REANIMATION DES CARDIOPATHIES ACQUISES

Objectifs glycémiques postopératoires : 5 – 8 mmol/L (0,9 – 1,5 G/L)

Modalités d'administration :

- Dilution : analogue ultra rapide de l'insuline I UI/mL dans NaCl 0,9 %
- Voie d'abord : robinet au plus proche du patient sur KTC ou sur VVP
- **Chez un patient diabétique insulino-dépendant, ne jamais arrêter insuline sans avis du MAR**

Version du 17/12/2020
Référents : J. Rey, N. Benillan, B. Bourdarias, A. Ouattara

Glycémie		0,4 g/L 2,2 mmol/L		0,6 3,3	0,9 5	1,1 6	1,5 8	1,8 10	2,5 14	3 16,5
Initiation insuline IVSE	Bolus IVD	0	0	0	0	0	0	3 UI	4 UI	6 UI
	Débit IVSE	0	0	0	1 UI/h si DT1 (Stop si DT2 ou non diabétique connu)		1 UI/h	2 UI/h	3 UI/h	4 UI/h Prévenir médecin
Fréquence des glycémies		15 min	30 min	1h	1h	2h	1h	1h	1h	1h

		Reprise à ½ débit quand : Glyc > 5,5 mmol/L chez DT1 Glyc > 10 mmol/L chez DT2								
G30 %		2 amp (6 g) Prévenir med	1 amp (3 g)	0						

Remarques :

Privilégier les glycémies capillaires sauf pour des valeurs dans les zones « rouges » (<0,6 ou > 2,5 g/L) qui doivent faire l'objet d'un contrôle de la valeur sur gaz du sang
Lorsqu'une nutrition ou alimentation entérale ou parentérale est initiée ou arrêtée, réaliser une glycémie 1H après (pensez à bien remplir la feuille des apports).
Surveillance du dispositif d'administration : PSE et voie d'abord!! (tubulures/robinet/VVC/VVP/VALVE ANTIRETOUR)
En raison d'interaction médicamenteuses, changer la seringue d'insuline toutes les 12 heures
Surveillance état de conscience si glycémie en zone rouge
Pas de sortie du patient dans les étages sous insuline IVSE. Sur avis médical, relais SC ou arrêt de la seringue. Modalités de relais sous-cutané (cf verso).

Protocole d'insulinothérapie IVSE PEROPERATOIRE DES CARDIOPATHIES ACQUISES

Objectifs glycémiques peropératoires : 5 – 10 mmol/L (0,9 – 1,8 G/L)
Modalités d'administration :
- Dilution : analogue ultra rapide de l'insuline I UI/mL dans NaCl 0,9 %
- Voie d'abord : robinet au plus proche du patient sur KTC ou sur VVP

Version du 16/04/2021
Référents : J. Rey, N. Benillan, B. Bourdarias, A. Ouattara

PASSAGE INSULINE IVSE / INSULINE SC

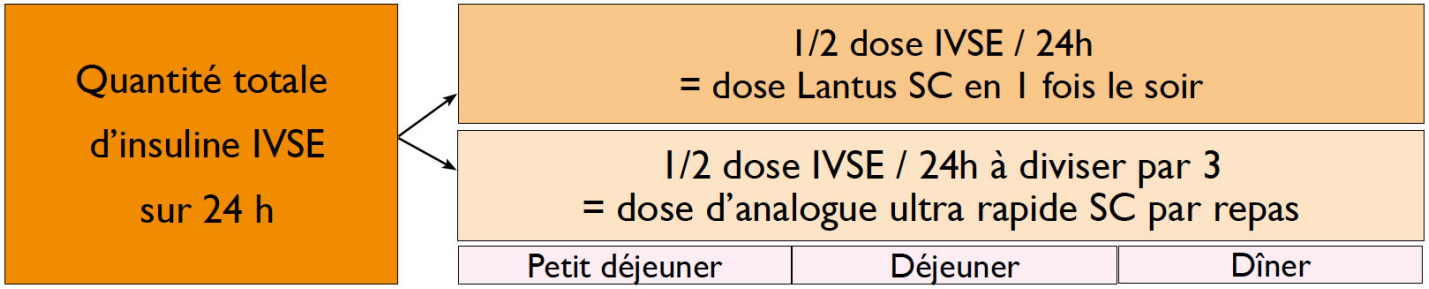
Indications

- Dès que les glycémies sont stables et ≤ 10 mmol/l
- A la reprise d'une alimentation orale
- Relais à l'arrêt de la seringue électrique d'insuline

Contre-indications

- Posologie d'insuline IVSE ≤ 0,5 UI/h
- Posologie d'insuline IVSE ≥ 5 UI/h
- Déséquilibre glycémique

Calcul de dose



Le délai entre l'arrêt de l'insuline IVS et l'injection de Lantus SC doit être IMMÉDIAT en préférant une injection à 20 h le soir. Si non faire une injection complémentaire selon le schéma suivant

Arrêt insuline IVSE	Entre 0 h et 6 h	Entre 6 h à 14 h	Entre 14 h et 18 h	Entre 18 h et 0 h
Dose de Lantus	3/4 dose	1/2 dose	1/4 dose	dose de 20 h
Dose de Lantus suivante	à 20 h le soir même			à 20 h le jour suivant

PAS D'INSULINE IVSE EN SALLE

Prise en charge pré opératoire (DT1 et DT2)

Règles de jeûne :

- Repas du soir normal
- Donner le traitement habituel : AD non insuliniques (sauf metformine) mais aussi insulines aux mêmes posologies
- Dernier repas solide à H-6 et liquides clairs autorisés jusqu'à H-2 de la chirurgie
- Mettre une VVP et perfuser avec soluté glucosé (G10% 40 mL/h) le matin à partir de 6-7h si et seulement si le patient a eu une insuline lente la veille au soir ou s'il a une pompe à insuline

Modalités d'arrêt des traitements antidiabétiques (AD) :

	Chirurgie ambulatoire	Chirurgie mineure ou majeure	Chirurgie urgente
Metformine	Pas d'arrêt	Pas de prise la veille au soir et le matin	Arrêt
Sulfamides	Pas d'arrêt	Pas de prise le matin	Arrêt
Glinides			
Inhibiteurs -glucosidases			
Inhibiteurs DDP-4			
Analogues GLP-1	Pas d'arrêt	Pas d'injection le matin	Arrêt
Insulines SC	Pas d'arrêt	Pas d'injection le matin (sauf dans le DT1)	Arrêt et relais
Pompe à insuline	Pas d'arrêt	Arrêt de la pompe à l'arrivée au bloc	Arrêt et relais

Période pré opératoire :

- Faire une glycémie capillaire avant le repas du soir, au coucher et à 6h et appliquer selon le protocole suivant :

<table>
<tr><td>Glycémie capillaire (GC)</td><td colspan="4">0,6 — 0,9 — 1,8 — 2,2 — 3 g/L
3,3 — 5 — 10 — 12 — 16,5 mmol/L</td></tr>
<tr><td>Avant le repas du soir</td><td>Sucre
15g PO
Prévenir le médecin</td><td></td><td>Insuline : analogue ultra rapide
3 UI SC | 4 UI SC
si correction non faite par le patient</td><td>6 UI SC + BU
Prévenir le médecin</td></tr>
<tr><td>19-20h</td><td colspan="4">Repas normal +/- insulines habituelles +/- AD non insuliniques sauf metformine</td></tr>
<tr><td>Au coucher 22h-0h
Si besoin 3h-4h</td><td>15g PO
GC à 15 min
Prévenir le médecin</td><td></td><td>3 UI SC | 4 UI SC</td><td>6 UI SC + BU
ou IVSE en réa
Prévenir le médecin</td></tr>
<tr><td>6h-7h</td><td colspan="3">Pas de prise d'AD non insuliniques
et G10% 40 ml/h si insuline lente la veille ou pompe à insuline en cours</td><td>VVP
NaCl 0,9%</td></tr>
<tr><td>Pré-op GC/3h</td><td>G10% 60 ml/h
Prévenir le médecin</td><td></td><td>3 UI SC | 4 UI SC</td><td>IVSE en réa
Différer le bloc</td></tr>
</table>

ATTENTION :

- Chez le patient DT1 et quelle que soit la glycémie :
NE JAMAIS ARRÊTER L'INSULINE LENTE

- Si hypoglycémie : Cf fiche
CAT devant une hypoglycémie à l'hôpital

- Si hyperglycémie : Cf fiche
CAT devant une hyperglycémie à l'hôpital

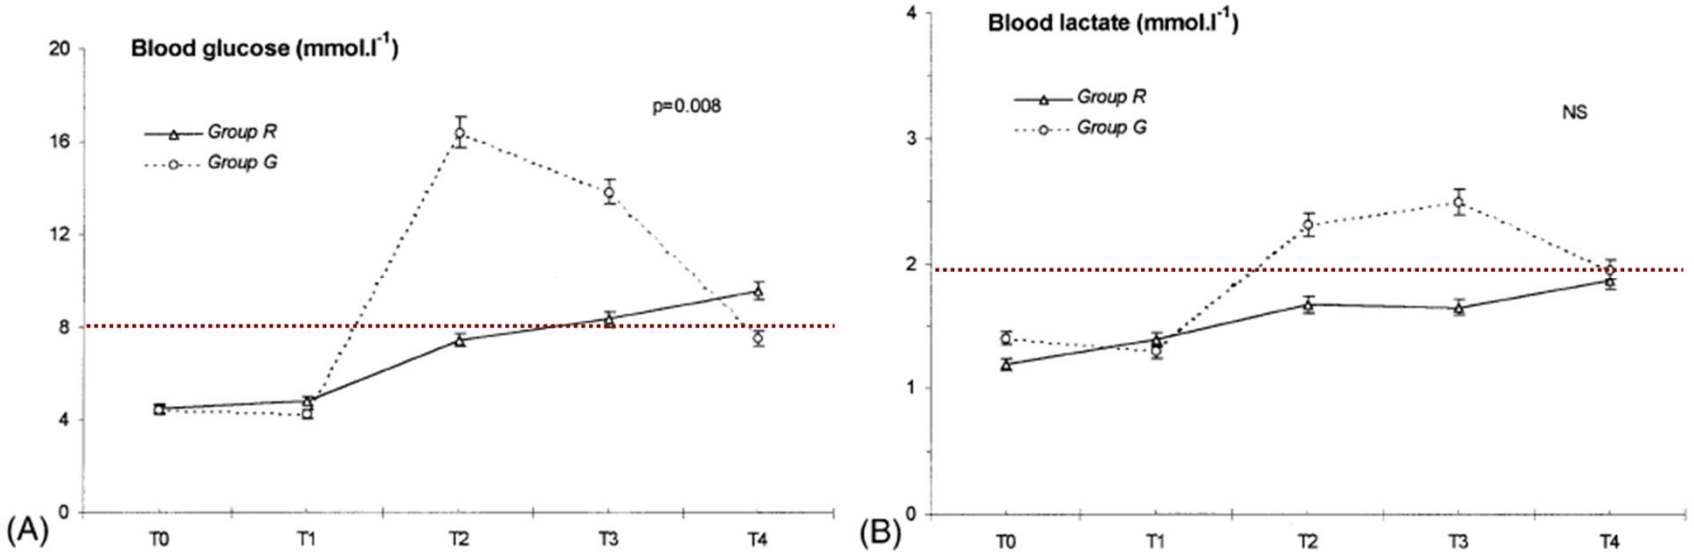
Groupe SFAR/SFD

Effects of Intraoperative Glucose Administration on Circulating Metabolites and Nitrogen Balance During Prolonged Surgery

Chambrier C et al. J Clin Anesth 1999; 11:646-51

Chirurgie abdominale ou thoracique ≥ 3 heures (ASA I-II)

Ringer lactate vs SG5% (10 ml.kg^{-1}.h^{-1} jusque H_2 postopératoire)



Si pas de glucose: pas d' hypoglycémie

Si apport de glucose= risque HG donc effets potentiellement délètéres

« …suggestions that glucose solutions should be avoided in both long and short surgical procedures. »

Conclusion

- Hyperglycémie périopératoire délétère chez patients diabétiques ou pas de chirurgie cardiaque
- Contrôle glycémique améliore leur «outcome »
- Insulinothérapie IV et relais sous-cutané
- Valeur seuil Peropératoire (<180 mg/dL)

  Réanimation (<150 mg/dL)
